Three other partners and a marriage of true minds are added in the summer of love... An industrialist's daughter is forced to marry a rich heir by her greedy grandmother as her adopted sister bonds with the charismatic wedding planner. Three other partners and a marriage of true minds are added in the summer of love...The present invention relates to an optical signal processing device, and, more particularly, to a device for processing a multiplexed optical signal having a plurality of channels each carrying a pulse train signal, such as optical pulse code modulation (pulse code modulation; PCM) signals. With the recent advent of wavelength division multiplexing (WDM) systems, high-speed and highly reliable optical communications have been possible. For example, there is a discussion about the use of the WDM system for the synchronous digital hierarchy (SDH) in the present Standardization Technical Conference in Japan (hereinafter called the "STD-3" discussion). In this STD-3 discussion, use is made of 10 Gb/s per channel as a standard data rate of the WDM system and a carrier transmission of a wavelength of about 1540 nm as an example of a transmission channel. In this STD-3 discussion, a multiplexed signal having 32 channels of 10 Gb/s each and a total transmission rate of 32*10 Gb/s will be transmitted. With the WDM system in such a high speed transmission, when an optical signal having a wavelength of about 1540 nm is amplified by a repeater, a dispersion arises in wavelength which is a wavelength characteristic of the transmission fiber, and therefore, the optical signal must be regenerated. FIG. 12 shows the overall structure of the conventional optical signal processing device. As shown in FIG. 12, an input optical pulse signal is inputted to an input terminal T101. A band pass filter having a predetermined center wavelength is provided in the input terminal T101, whereby a received optical signal containing a channel for the 1540 nm band is provided from the input terminal T101. The received optical signal is supplied to a demultiplexer 100 which demultiplexes the received optical signal into 32 channels of signals each having a predetermined center wavelength. The demultiplexer 100 is controlled by a clock signal in a synchronous system. The demultiplexed optical signal is inputted to an amplifier 102 and an optical repeater 103. The amplifier 102 is controlled by a clock signal in 82157476af
